

Kill Your Darlings: Image Selection

Fabiana Alves Ferreira

Every image in the final set is real — no AI-generated image was approved in this round. The three generated images were tested and rejected, with the reason documented below.

Final set — approved images

1. Personal photo (About / Contact)

Real photo, no background edits. The background is naturally out of focus from the camera's depth of field, so the face stays the sharpest, most eye-catching part of the image — meets the requirement of using a real photo for anything related to the person.

2. Brigadeira Stock project screenshot — code (Case study)

Real screenshot of VS Code, showing the actual folder structure (Controllers, Models, Migrations) and the .csproj file with the project's real dependencies (SQLite, Entity Framework). Concrete, legible proof of the work, with no AI-generated elements.

3. Brigadeira Stock project screenshot — running site (Case study)

Real screenshot of the system running on localhost — the Brigaderia Stock homepage, with the navigation menu (Principal, Produto, Categoria) and the footer identifying the Univesp capstone project (Projeto Integrador). Shows the working result, complementing the code screenshot: one proves the process, the other proves the delivered product.

4. Chile street — illustrative image (Case study)

Google Street View capture (a public tool) — not a real address from the TeleDesign project, used only to visually represent the type of street-by-street verification done during the project. No client or real project information is shown or implied here, preserving the confidentiality of the company's information.

Rejected images

Three Gemini-generated variations — 'data scientist in a sophisticated office'.

I generated three variations of a "data scientist in the office" scene using Gemini, and rejected all of them. They depict me in a way that never happened — the assignment calls for a real photo for anything related to me, not an AI-fabricated face. On top of that, they had clear generation errors (illegible code text on the screens, a loose Arduino/protoboard with no context in one version) and the generic 'floating hologram' and glass-panel look that this week's material explicitly warns against.

Connective elements (icons, textures)

Conscious decision not to include any AI-generated element at this stage — including the simple icon set tested separately. The portfolio uses only the three real images above, following the material's own guidance: a restrained composition showcases the work better than decorative elements. Future review: once the full site is assembled, revisit as a whole whether any supporting visual element is worth adding.
