

FLYRANK AI — FOUNDATIONS

(Week 2)

Prompt Iteration Log

Fabiana Alves Ferreira

1. Task chosen

FL-01 target task: "Tailoring my resume for a specific job." Job used: Ab InBev — Data Quality Engineer (focus: Data Quality, ETL, SQL, Python, data testing). Base material: Fabiana's real resume and the Week 1 proof statement (Chile / TeleDesign).

2. Version 1 — Naive prompt (baseline)

Prompt: "Tweak my resume for this Data Quality Engineer job."

Output (summary): Generic advice disconnected from the actual resume: "add keywords like SQL, ETL and Python", "use action verbs", "be more concise". No sentence from the resume was rewritten; no reference to the real job posting or to Fabiana's story.

Note — what changed and why: Nothing changed yet: this is the baseline for comparison. The prompt provides no resume, no job posting, and no context, so the AI answers with generalities that apply to anyone — the equivalent of generic HR-blog advice. Risk: without real context, the AI may suggest jargon that doesn't match the actual experience.

3. Version 2 — Role assignment

Prompt: "You are a senior Data Quality Engineering recruiter with 10 years of experience screening junior resumes for ETL, SQL and Python roles. Evaluate the resume below for the Ab InBev Data Quality Engineer role (focus: Data Quality, ETL, SQL, Python, data testing) and point out what to strengthen." [+ full resume pasted]

Output (summary): Specific, prioritized feedback: identifies that the line "ensured the quality and integrity of internal databases, eliminating duplicates" (Padma) is the strongest Data Quality signal on the resume, but it's buried mid-document. Recommends pulling it up. Flags that the Churn project (Python/SQL) should appear earlier. Flags that "data testing" doesn't explicitly appear in any listed experience.

Note — what changed and why: Assigning a specific role (senior DQ recruiter) changed both the vocabulary and the evaluation criteria: the output moved from generic advice to a prioritized read (what to pull up vs. what's a weak signal), because the AI now evaluates the way someone who has screened hundreds of similar resumes would, not as a neutral assistant.

4. Version 3 — Context and motivation

Prompt: Same prompt as V2, plus: "Context: I'm transitioning my career into data. My proof statement is: 'I identify inconsistencies in raw data and verify information against reliable sources before they cause rework — like when I validated illegible addresses for a network project in Chile, street by street, using Google Earth.' The goal is for a data manager to schedule a conversation with me. Never invent or exaggerate experience — every sentence must stay 100% true."

Output (summary): The AI started tying suggestions back to the proof statement: it recommends that the "eliminating duplicates" and "ensuring integrity" lines become the resume's throughline, not standalone items.

Importantly, it explicitly refused to suggest "automated data testing frameworks" since there was no evidence of that in the resume, suggesting instead the honest phrase "structured data validation via SQL and manual review".

Note — what changed and why: Adding the proof statement and the anti-invention instruction changed the AI's behavior in a measurable way: in V2 it nearly suggested jargon ("automated testing") that didn't match the real experience; in V3, with the explicit warning, it flagged the gap itself instead of filling it with invention. This is the practical effect of the project's "never invent facts" criterion.

5. Version 4 — Few-shot examples

Prompt: Same context as V3, plus one full example: "Before: 'Ensured the quality and integrity of internal databases, eliminating duplicates.' After: 'Ensured the quality and integrity of internal databases, eliminating recurring duplicates and reducing operational rework — Data Quality discipline applied day to day.' Apply this same pattern (action + result + explicit connection to Data Quality) to the other experiences (Padma and Metaltex)."

Output (summary): All remaining Padma and Metaltex lines were rewritten following the same three-part mold. The result was consistent in format and tone — but repetitive: nearly every sentence ended with some variation of "Data Quality discipline applied to X", which reads mechanically if used without review.

Note — what changed and why: The example acted as a mold and guaranteed structural consistency between sentences — solving V3's tone inconsistency. But it exposed a new problem, visible only by comparing outputs: the AI over-generalized the example's pattern, applying the same formula repeatedly. This shows that few-shot improves consistency but needs to be paired with a variation instruction to avoid sounding robotic.

6. Version 5 — Output structure

Prompt: Same context as V4, plus: "Deliver the answer as a table with three columns: Original | Suggestion | Justification (max 20 words each). At the end, also rewrite the professional summary in 3 lines."

Output (summary): A clean, row-by-row table, each original sentence next to its suggestion and a short justification — easy to approve or reject item by item. The final professional summary came out as 3 focused lines, citing SQL, Python and Data Quality right at the start.

Note — what changed and why: Requesting a specific output structure solved the practical review problem: instead of a dense paragraph that's hard to compare against the original resume, the table lets her decide row by row in a few minutes — hitting directly the 'the edit takes under 20 minutes' criterion defined in FL-01.

7. Version 6 — Step decomposition (final prompt)

Final prompt: "You are a senior Data Quality Engineering recruiter evaluating resumes for the Data Quality Engineer role at Ab InBev (focus: Data Quality, ETL, SQL, Python, data testing). Context: I'm transitioning my career into data. My proof statement is: [paste]. The goal is for a data manager to schedule a conversation with me. Never invent or exaggerate experience. Do this in steps: (1) list the 6-8 core keywords from the job posting; (2) for each one, say whether the resume has real evidence (match) or not (gap) — don't invent matches; (3) rewrite only the items with a real match, following the pattern action + result + connection to the keyword, varying sentence structure; (4) for real gaps, suggest how to name them honestly. Deliver as a table: Original | Suggestion | Justification (max 20 words). [paste resume]"

Output (summary): Step 2 (match vs. gap) explicitly revealed that 'formalized data testing' is a real gap — and the AI suggested naming it honestly as 'structured data validation via SQL', instead of inventing it. Step 3 avoided V4's mechanical repetition, because the instruction asked for sentence variation. The final table was ready for direct use.

Note — what changed and why: Step decomposition was the technique that changed the outcome the most: forcing an explicit 'match vs. gap' step before rewriting any sentence prevented the biggest risk of the whole exercise — inventing experience (which nearly showed up in V2). Separating 'mapping' from 'rewriting' also solved V4's repetition problem, because the rewrite step now started from a verified mapping, not a single generic example.

8. Cross-model comparison — Claude vs. ChatGPT

The Version 6 final prompt was run on both models, with the same resume. Honest, point-by-point comparison:

Structure: Nearly identical — both delivered the keyword table (match/gap) followed by the Original | Suggestion | Justification table, exactly as requested in step 4 of the prompt. Both followed the instruction equally well here.

Accuracy / the most important finding: ChatGPT caught an error left in the prompt itself: the proof statement field hadn't actually been filled in (it was still the literal placeholder "[paste]"), and it flagged this explicitly, refusing to invent a match from an empty field. Claude, on the same run, did not flag this — it proceeded assuming the proof statement context was implied. This is a real behavioral difference, not a style difference: ChatGPT was stricter about calling out the user's own execution error.

Depth of analysis: ChatGPT separated out 8 keywords (including ETL/Data Pipelines and Data Modeling as distinct items) and classified evidence by source — professional, project, academic, technical. Claude, in V6, treated the resume in a more unified way, with less granularity in that breakdown.

Initiative beyond the requested scope: ChatGPT proactively suggested rewriting the "Objective" line at the top of the resume (from "Jr. role in Data Analysis and Operations" to something like "Data Quality Engineer Jr. | Data Quality, SQL and Python") — a structural change the prompt didn't explicitly request, but one that is strategically relevant. Claude did not touch that line.

Common ground (the most important point for the project's honesty criterion): Both models converged exactly where it matters most: neither invented ETL experience or automated data testing experience. Both named these gaps with the same honest language ("data extraction and processing", not "ETL pipeline"). This confirms that the step-decomposition technique (Version 6) works consistently across models — it isn't a behavior specific to just one.

Weak point identified: Claude was less rigorous about flagging the prompt's fill-in failure (the empty "[paste]" placeholder) — a real recruiter would notice this immediately, so ChatGPT's check here has real practical value, not just style.

9. Reusable prompt template (final template)

Generic version, with no personal data from Fabiana, applicable by anyone to any resume + job pair:

You are a senior recruiter specialized in [JOB FIELD] evaluating resumes for the [ROLE] position at [COMPANY], whose stated focus is [JOB KEYWORDS].

Context: this resume supports the following statement about me: "[YOUR PROOF STATEMENT / VALUE SUMMARY]". It's essential that no adjustment invents or exaggerates experience — every sentence must stay 100% true.

Do this in steps: (1) list the 6-8 core keywords from the job posting; (2) for each one, say whether my resume has real evidence (match) or not (gap) — don't invent matches; (3) rewrite only the items with a real match, following the pattern action + result + explicit connection to the keyword, varying sentence structure; (4) for real gaps, suggest how to name them honestly, without pretending to have experience that doesn't exist.

Deliver as a table: Original | Suggestion | Justification (max 20 words).

10. Summary of techniques applied

Version	Technique	Main observed effect
1	None (baseline)	Generic advice, no use of the real resume
2	Role assignment	Prioritized feedback, recruiter vocabulary
3	Context and motivation	Connection to the proof statement; AI refused to invent
4	Few-shot examples	Format consistency; risk of mechanical repetition

5	Output structure	Reviewable table in minutes, not a dense paragraph
6	Step decomposition	Separated mapping from rewriting; eliminated the invention risk
